

# TD N-Lateration, Static-Fingerprint, and Mobility Prediction with HMM

By Philippe Canalda

## Introduction

These slots of 2 hours of directed works provide the opportunity to co-conceive and to implement various basic software components helpfull for modern applications wherin positioning and dynamic mobility are crucial.

## Summary

## TD n° 2 N-Lateration

The objective is to conceive and implement, with the language of your choice, the basic N-lateration algorithm. In this directed work, I will propose a global architecture view of an indoor positioning scenario involving  $N=4$  Access Points and an object/human identified as a Mobile Object (Terminal). 2 approaches based, either on model propagation, or Time of Fligth, provide distances between Emitters and Receivers.

N-lateration requires  $N$  Emitters and 1 Receiver or 1E-NR.

To geolocalize, or to position in a  $N$  dimension environment, that requires, at least  $N+1$  distances between Emitter and Receiver which are not co-linear.

In a corridor (2D), at least 2 distances are required. In a plan, 3 circles. In a 3D space, 4 satellites and a GPS receiver or 1 Emitter and 4 Receivers in infrastructure-centric positioning system.

But, take care that knowing  $d(E,R)$  is not sufficient when line of sight are not guaranteed or when speed-up happen (due to heterogeneity of densities, due to electro-magnetic strength, etc.).

See below the indoor environment to be considered. We need a picture of the environment and a cartesian referential where the origine is placed in the up and left corner, the X axis is right oriented and Y axis is down oriented. We provide a data set composed of 4 distances between  $E_i$  emitters and a receiver. The position of emitters are known.

The work to do is :

1. Design the V1 version of the implementation (following scrum/agile methodology), which favorize the time to validation of positioning technic implementation ;
2. Propose the Object Class Diagram with prioritized functions ;
3. Conceive the two main algorithms :
  - a. The N-lateralation algorithm which compute the estimated position by minimizing the sum of distances to 4-spheres inside the perimeter of the 4 spheric volumes aggregated ;
  - b. The factory design pattern (for the given data set) ;
4. Compare the result provided by your implementation with a geometric resolution of the senario provided.

As Annexe 1, 5 pictures which illustrate the resolution of this problem.

Below some information to better understand the overall problem.

$d=c \times t$  the celerity model

$$\frac{P_e}{P_a} = \frac{G_{ae} \times G_{ar} \times \lambda}{4 \pi d^2} \left( \frac{r}{d} \right)^2$$

the Friis attenuation propagation model

Input data set :

| $E_i$   | Center (of the AP, the satellite, etc.) | Distance to receiver (samrtphone) |
|---------|-----------------------------------------|-----------------------------------|
| $i = 0$ | (0,5 ; 0,5 ; 0,5)                       | 3                                 |
| $i = 1$ | (4 ; 0 ; 0)                             | 2                                 |
| $i = 2$ | (4 ; 5 ; 5)                             | 4,2                               |
| $i = 3$ | (3 ; 3 ; 3)                             | 2,5                               |

The estimate position minimize the sum of distances to all spheres.

## TD n°3 Fingerprint

This directed work session consists in building a matrix of an environment. Each case of the environment is characterized with informations :

- Geographic information, for examples :

- o Latitude, longitude, altitude (universal or global reference system of positioning);
- o The postal address, the stage, the room ;
- o The relative positioning in a 2D plan or 3D plan (local reference system of positioning) ;

- Descriptive information :

- o Signal : Received Signal Strength, Emitted Signal (power) Strength, wave orientation, ratio RSS/ESS => wave propagation model (Friis, ...)
- o Quality of communication : received messages over emitted, packet losses, number of damaged messages, ...
- o But also

- Needs to catch the actual environment photography of either the MT (Terminal-centric PS) or each component of the infrastructure-centric PS
- Then determine by matching the k best fingerprint closest to the caught environment (above) and determine by weighted barycenter computing the positioning of the Object or Human

Below a wrong implementation (I mean with mistakes) of fingerprint implementation.

Consider a rectangle area 12m x 12m of 9 square of 4m x 4m. the left upper side is (0,0) origine. Then each centrum of area can be easily deduced.

In the implementation below, fingerprint initialisation are good, also the RSSI vector of the Mobile Terminal.

But the barycentric ponderation is false.

Determining the k-neighbouring for the k better cells, those cells which have the best minimization of RSSI differences, that allows to determine the distances  $d_1, \dots, d_k$ .

And knowing  $d_1$  and  $d_2$ , it is possible to deduce an expression of coefficient  $c_2$  in terms of  $c_1$ . Such that  $OM = c_1 OK_1 + c_2 OK_2 + \dots + c_k OK_k$ , with  $c_1 + \dots + c_k = 1$ .

if  $d_1 \times \alpha = d_2 \Leftrightarrow c_2 = (1/\alpha) c_1$

We do the same for  $c_3$  and  $c_4$ . Then we can determine the value of  $c_1$ , then  $c_2$ , etc.

And then we can resolve the coordinates of the Mobile Terminal TM.

You have to implement it.

```

import java.lang.reflect.Array;
import java.util.Arrays;

/**

## TD n°1 Markov Model usefull for anonymisation and for prediction (positioning and action)

Chaîne de Markov

### What is Markov Model or Hidden Markov Model ?

An interesting computer science object interesting to :

- modelize an automata,
- a statistical and valued graph

which allows, firstly to summarize actions performed (the history of), and secondly which predicts the next position or action, or/and the previous position or action.

MM is composed of nodes and transitions.

### Localization Graph or Positioning graph

Another example of resolution :

The screenshot shows the Eclipse IDE with the file 'whereGoMM.cpp' open. The code is a C++ program that initializes a 5x5 matrix, sets a current location, and enters a loop where it asks the user for a next location. The console output shows the program's execution, including the matrix initialization, the current location, and the user's input for the next location.

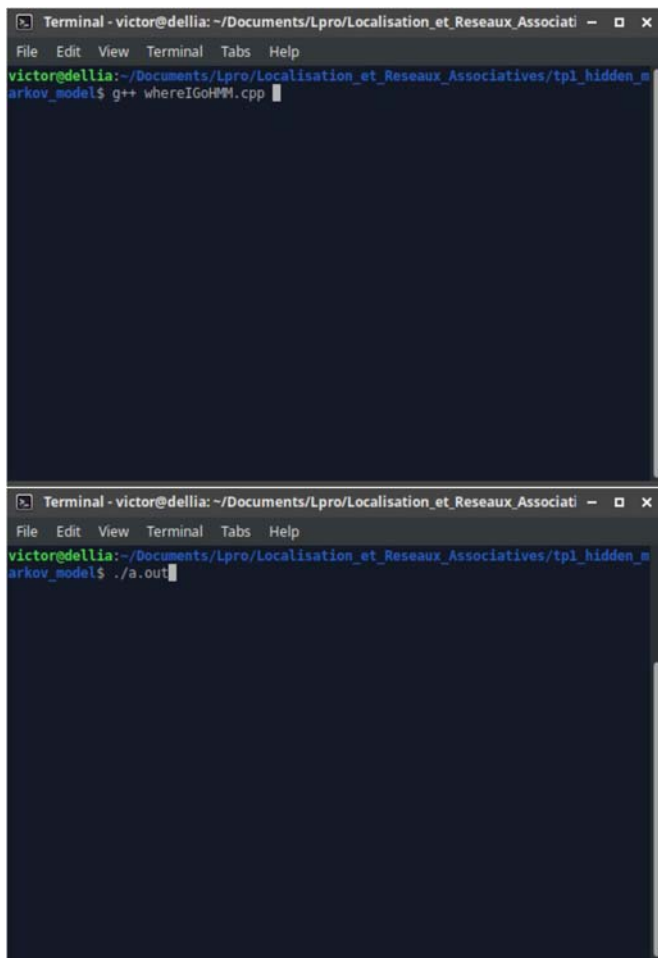

```
53 int main() {
54
55     //Initialisation de la matrice qui contiendra la HMM
56     int rows = 5, columns = 5;
57     MatrixElement matrix[rows][columns];
58
59     for(int iRow = 0; iRow < rows; iRow++) {
60         for(int iColumn = 0; iColumn < columns; iColumn++) {
61             matrix[iRow][iColumn] = MatrixElement(0, 0.0);
62         }
63     }
64
65     std::string previousLocation = "/";
66     currentLocation = "0";
67     nextLocation = "";
68     int nextLocation = -1;
69     cl, //current location
70     nl,
71     lineCount; //next location
72
73     while(nextLocation != "Q") { // Q: quit program
74
75         std::cout << "where you from: " << previousLocation << std::endl;
76         std::cout << "where you are: " << currentLocation << std::endl;
77         std::cout << "where you go: (please enter a number 0-4, q: quit, Q: Quit program)" << std::endl;
78
79         bool isUserInputCorrect = false;
80
81         while(!isUserInputCorrect) {
82
83             std::cout << "> ";
84             std::cin >> nextLocation;
85             isUserInputCorrect = true;
86         }
87     }
88 }
```

To compile and execute :

The first screenshot shows the terminal window with the command 'g++ whereGoMM.cpp' entered. The second screenshot shows the terminal window with the command './a.out' entered, which executes the compiled program.

```
victore@delia:~/Documents/Lpro/Localisation_et_Réseaux_Associati...  
arkov_model$ g++ whereGoMM.cpp
```

```
victore@delia:~/Documents/Lpro/Localisation_et_Réseaux_Associati...  
arkov_model$ ./a.out
```
